

Is Contact Solution Saline Solution

Introduction

If you wear contact lenses, you have likely asked yourself: **Is contact solution saline solution?** It is a common point of confusion, especially for new lens wearers who see the words “saline” on some bottles and “contact solution” on others. The short answer is no—they are not the same. While both are used in lens care, they serve very different purposes. Using the wrong one can put your eye health at risk. In this article, we will break down the differences, explain what each product is designed for, and help you make informed choices for your daily lens routine.

Understanding Contact Lens Solutions

To understand why contact solution is not simply saline, we need to look at the ingredients and functions of each type of product. The market offers several categories, each with a specific role in cleaning, disinfecting, rinsing, and storing lenses.

What is Saline Solution?

Saline solution is a sterile mixture of sodium chloride (salt) and purified water, typically at a concentration of 0.9% salt—similar to the natural salinity of human tears. It is primarily used for **rinsing** contact lenses after cleaning and for **storing** lenses in a case, but only if it is a preserved saline solution. Unpreserved saline, often sold in single-use vials, is intended for rinsing only and should not be used for long-term storage because it lacks preservatives to prevent bacterial growth.

Critical fact: **Saline solution does not contain any disinfecting agents.** It can rinse away loose debris and dust, but it will not kill bacteria, fungi, or viruses. This is the fundamental distinction when comparing saline to multipurpose contact solution.

What is Multipurpose Contact Solution?

Multipurpose solution (MPS) is the most common type of contact lens care product. It combines several functions in one bottle: cleaning, disinfecting, rinsing, and storing. MPS contains **preservatives and disinfectants** such as polyaminopropyl biguanide (PHMB), polyquaternium-1, or aldox. These agents actively kill microorganisms that can accumulate on lenses during wear.

Multipurpose solutions also include surfactants that help remove lipid and protein deposits from the lens surface. When you rub and rinse your lenses with MPS, you are physically and chemically removing debris while also disinfecting. After this process, you store the lenses in fresh MPS, which keeps them sterile overnight.

Hydrogen Peroxide Systems

A separate category is the hydrogen peroxide-based system (e.g., Clear Care). This solution uses 3% hydrogen peroxide to provide a powerful disinfecting action—more aggressive than most MPS products. After a required neutralization step (usually with a special case and a catalytic disc), the solution converts to a gentle saline that is safe for the eyes. **Hydrogen peroxide systems should never be placed directly into the eye** without neutralization. They offer an excellent alternative for people with allergies to MPS preservatives, but they are still a true contact solution, not simply saline.

Key Differences Between Saline and Contact Solution

Now that you understand what each product is, let’s compare them head-to-head across the functions that matter most for lens care.

Cleaning and Disinfecting Ability

The biggest difference is antimicrobial activity. **Saline solution has zero disinfection power.** It is merely salt water. If you store lenses in saline alone, bacteria and fungi can multiply rapidly on the lens surface, leading to serious eye infections such as microbial keratitis. Contact solutions—whether multipurpose or hydrogen peroxide—are specifically formulated to kill pathogens. The FDA requires these products to pass strict efficacy tests against common contaminants like *Pseudomonas aeruginosa* and *Staphylococcus aureus*.

Storage and Soaking

For overnight storage, you must use a solution that keeps lenses hydrated and sterile. Multipurpose solutions and properly neutralized hydrogen peroxide systems both maintain sterility. Saline, unless it is a preserved version (which still lacks disinfectants beyond a mild preservative), is **not recommended for storage**. Many unpreserved saline products are labeled “for rinsing only” for this reason. Using them for storage creates a breeding ground for microbes.

Enzyme Removal

Some contacts, especially those with high water content or extended-wear lenses, can accumulate protein deposits. Many multipurpose solutions now include low-level enzymatic activity (e.g., with agents like hyaluronan or poloxamine) to help break down these deposits. Saline solution does not

contain any enzymatic cleaners. Relying solely on saline may lead to discomfort, blurred vision, and reduced lens lifespan.

Why You Should Not Use Saline as a Substitute

The question “Is contact solution saline solution?” often arises when someone runs out of their regular product and reaches for a bottle of saline. This is a dangerous shortcut.

Risk of Eye Infections

According to the American Academy of Ophthalmology, the most common cause of contact lens-related corneal infections is improper hygiene, including the use of saline for disinfection. A study published in *Eye & Contact Lens* found that patients who used only saline for storage had a significantly higher incidence of microbial keratitis. Symptoms include redness, pain, light sensitivity, and discharge. In severe cases, infections can lead to corneal scarring and vision loss.

Ineffective Against Microorganisms

Saline cannot kill amoebae such as *Acanthamoeba*, which is particularly dangerous for contact lens wearers who rinse lenses with tap water or homemade saline. Even commercial sterile saline lacks the biocides needed to eliminate these pathogens. Multipurpose solutions, especially those containing PHMB or polyquaternium-1, are active against Acanthamoeba cysts (though no solution is 100% effective). Using saline as a substitute increases your vulnerability to this rare but devastating infection.

Proper Use of Contact Lens Solutions

To keep your eyes healthy, follow a consistent care routine. Understanding the correct role of each solution type is essential.

Daily Cleaning Routine

- Wash and dry your hands** thoroughly before handling lenses.
- Remove one lens** and place it in your palm. Apply a few drops of multipurpose contact solution (not saline).
- Rub the lens gently** for about 20 seconds on each side using your fingertip. This mechanical cleaning removes debris and biofilm.
- Rinse the lens** with a stream of fresh multipurpose solution (or with saline if you are following a hydrogen peroxide system’s rinsing step; check the instructions).
- Place the lens in a clean case** filled with fresh solution. Never “top off” old solution.
- Repeat for the second lens.**
- Close the case tightly** and store it upright at room temperature.

Storage and Replacement

Always use the solution recommended by your eye care professional. Multipurpose solutions are safe for storing lenses for up to 30 days in a sealed case (change the solution daily). Hydrogen peroxide systems require special cases and a neutralization time of at least 6 hours. **Never store lenses in plain saline.** Also, replace your lens case every three months to prevent biofilm buildup.

Common Misconceptions

- **“Saline is safer because it has fewer chemicals.”** In reality, the lack of chemicals makes saline unsafe for disinfection. The “chemicals” in contact solution are necessary preservatives and disinfectants at safe, regulated levels.
- **“I can use eye drops as a substitute for solution.”** Lubricating eye drops (artificial tears) are not sterile for long-term storage and do not disinfect. Only use approved lens rewetting drops.
- **“Saline is the same as contact solution because both are sterile.”** Sterility at the time of manufacture is not the same as sustained antimicrobial activity. Saline becomes contaminated quickly once opened.
- **“Homemade saline is just as good.”** Homemade salt water cannot be sterilized reliably and lacks any preservative. This is extremely dangerous and can lead to serious eye infections.

Conclusion

So, is contact solution saline solution? **Definitely not.** While saline solution is a sterile salt-water mixture useful for rinsing certain types of lenses or as part of a hydrogen peroxide system, it does not clean, disinfect, or safely store contact lenses on its own. Multipurpose contact solutions and hydrogen peroxide systems are specially formulated to kill microorganisms, remove deposits, and keep your lenses safe for repeated wear. Using saline as a substitute places your eye health at risk of infections that can cause lasting damage. Always follow the guidance of your eye care professional and read product labels carefully. When in doubt, remember: for cleaning and storing, stick with a true contact lens solution—not just saline.
